Learn Open Redirect – Sample Guide

Open Redirect is a web application issue where an application redirects users to a URL influenced by user input without proper validation. Attackers may abuse this in phishing campaigns or to bypass trust checks.

Common Causes

- Redirect parameters are not allowlisted.
- User-controlled URLs are trusted directly.

Potential Impact

- Phishing
- Reputation damage
- Chaining with other vulnerabilities

Mitigation

Use allowlists for redirect destinations, validate IDs instead of full URLs, display confirmation for external redirects, and log unexpected redirect attempts.
